ScreenSense: Key Insights & Recommendations

Actionable findings from kids' screen time behavior analysis

KEY FINDINGS

- Average daily screen time is 4.37 hours, with over 91% of children exceeding recommended limits
- High-risk users constitute ~85% of the dataset, indicating widespread overexposure
- Screen time increases significantly with age, peaking in the 17–18 age group
- Recreational usage dominates across all age groups (~75–80%)

BEHAVIORAL INSIGHTS

- Teenagers (14–18) show the highest engagement, primarily driven by smartphone usage
- Younger children (8–10) demonstrate relatively higher educational usage compared to older groups
- Urban users exhibit higher total usage, especially in recreational activities
- Gender differences are minimal, indicating screen usage is behaviorally consistent across genders

RISK & HEALTH INSIGHTS

- Increased screen time strongly correlates with higher health issues (poor sleep, eye strain)
- Majority of health issues are concentrated among users exceeding screen limits
- Smartphones are the primary contributors to health-related risks due to prolonged usage
- High screen time cohorts (>6 hrs) show significantly elevated risk levels

DEVICE INSIGHTS

- Smartphones dominate usage (~47%), making them the primary driver of screen exposure
- Tablets are more common among younger users, while laptops are used for educational purposes
- TV usage remains secondary but still contributes significantly to total screen time
- Device preference shifts from shared (TV/tablet) to personal (smartphone) with age

RECOMMENDATIONS

- Introduce screen time caps and parental controls, especially for teenagers
- Promote educational content consumption to balance recreational usage
- Encourage device-free routines (e.g., before sleep) to reduce health risks
- Schools and policymakers should design awareness programs targeting high-risk cohorts
- Prioritize smartphone usage monitoring, as it is the largest contributor to excessive screen time
